The Conservability of a Latent Image and of Sensitivity in Nuclear Photoemulsions Sensitized by Triethanolamine

during the irradiation (and especially not due to the absorption of the halogen separated out by the radiolysis of AgHal). Beginning with the formation of subcenters, the presence of triethanolamine in the emulsion is not of essential importance and the subsequent variation of the properties of the emulsion is determined by the presence of subcenters in the crystals. The decrease of triethanolamine in alkalinity (by adding acids which do not react with AgHal) diminishes its sensitizing effect. The experiments discussed in the present paper prove the sensitizing and also the stabilizing effect of triethanolamine in complete agreement with the mechanism of its interaction with the crystals of the photoemulsion. There are 3 tables and 7 references, 5 of which are Soviet.

TITLE: Letter to the Editor; The Effect of Not Substitutability at Photographic Activity of β -Radiation

PERIODICAL: Zhurnal nauchnoy i prikladnoy fotografii i kinemato-grafii, 1959, Vol 4, Nr 4, pp 301-303 (USSR)

ABSTRACT: The authors state, that the effect, described by Ray and Stevens Ref 17, demands a dependency in particular between its value, the limit of its existence on the one hand and the ionizing power of β -particles, the sensitivity of the emulsion on the other hand. The tests were made on electronographic plates, which are sensitive towards β -particles, low sensitive dia-positive plates, and on nuclear emulsion type R NIKFI, with the highest sensitivity of all emulsions towards particles. As radiation source isotopes with pure β -radiation were used: P^{32} and C^{14} in Na_2HPO_4 and Na_2CO_3 . The results confirmed the existence of the

TEXT: In an earlier paper by the present author and Soltitskiy (Ref.1) it was found that the reciprocity law breaks down in the case of β-particle induced images. Since it was suspected that this effect is due to regression, an investigation was made of the dependence of this effect on temperature. Three emulsions were exposed using C¹⁴ and P³² β-sources. They were: nuclear emulsion of type NIKFI-P (NIKFI-R), electron diffraction emulsion, and a diapositive emulsion. The temperature range investigated was 0 to 40°C. The humidity was kept constant and approximately equal to normal room humidity. It was found that Meikler's equation (Ref.2)

$$H = \frac{H_0}{2} (1 + \sqrt{1 + bt})$$

TITLE: The Energy of the Activation of the
Thermal Fading of a Latent Photographic Image

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol 131, Nr 1, pp 64 - 67
(USSR)

ABSTRACT: The results given in the present paper also contain several data, which were determined by the method developed by P. V. Meyklyar. This method is based on the analysis of curves, which express the impossibility of substituting (of the so-called iso-opaque places) photographic layers within the range of long exposure times. The method in principle permits determination of the number of Ag atoms in the subcenter and the activation energy of an arbitrary group of atoms which is not larger than a subcenter. The authors first modify and supplement Meyklyar's method to a certain extent. The corresponding formulas are derived step by step and are explicitly written down. The experimental investigation was carried out on a fine-grained silver bromide emulsion, which had not been ripened a second time. The plates with the emulsion to be investigated were exposed for from 1 to 10⁴ sec (sometimes also 10⁵ sec) through a

Card 1/3

of a Latent Photographic Image B013/B007

stepped wedge at temperatures of + 40, + 20°, and, in some cases also at 0°, after which they were developed in an Amidol developer according to the two-temperature dry process. The extreme inclination 1/2 (the Schwartzschild exponent p also equals 1/2 and the number n of atoms in the subcenter equals 2) was found only near the blackening threshold (blackening density $D < 0.1$). To the extreme inclination 2/3 ($p = 1/3$, $n = 3$) there corresponds $D \sim 0.6 - 0.8$, and with a sufficiently large D ($\sim 1.5 - 1.8$) the extreme inclination attains 3/4 ($p = 1/4$, $n = 4$). Figure 1 shows the iso-opaque places for the three aforementioned values of D. From table 1 the increase of the activation energy U_1 with a decrease of the center consisting of i atoms may distinctly be seen. This increase is apparently slower than linear. The activation energy is approximately equal in all cases in which the Ag-particle lacks a total of one atom for stability. The stability of the center is thus due to the activation energy attaining a certain value, independent of the number of Ag-atoms required for this purpose. The efficacy of the sensitivity center must here be understood to be the depth of the corresponding "energy trap". The more

difficult the formation of the latent image, the more Ag-atoms
are required for the purpose of obtaining an image of critical
extent (which suffices for the subsequent catalysis of the
image). There are 1 figure, 1 table, and 7 references, 6 of
which are Soviet.

AUTHOR: Kartuzhanskiy, A.L.

TITLE: Experimental determination of the activation energy
of the thermal resorption of latent-image centres
of various dimensions

PERIODICAL: Referativnyy zhurnal, Khimiya, no.11, 1962, 68,
abstract 11 B 424. (Zh. nauchn. i prikl. fotogr. i
kinematogr., v.6, no.6, 1961, 449-450).

TEXT: A method is proposed for the experimental
determination of the energy of activation for the thermal
resorption (U_i) of centres of the latent image (LI), consisting
of different numbers i of Ag atoms. The method is essentially:
if from experiments on mutual irreplaceability under the action
of particles A, B, C with various ionizing abilities the values
 U_{iA} , U_{iB} , U_{iC} were obtained, then the dimensions of the
corresponding centres LI i_A , i_B , i_C can be obtained from
analysis of the isoopacity for threshold developing times

Card 1/2

Experimental determination of ...

E111/E152

t_A , t_B , t_C (the developing times at which individual traces of particles become just distinguishable), in their turn determined from curves of the kinetic development of traces of particles A, B, C. The isoopacities are constructed for a density close to the darkening threshold, for example about 0.1 above the fog. By this method the relation $U = f(i)$ was obtained for certain nuclear emulsions.

AUTHOR: Kartuzhanskiy, A. L.

TITLE: The phenomenon of the noninterchangeability in the photographic effect of nuclear radiations.

SOURCE: Yadernaya fotografija; Trudy Tret'ego Mezhdunarodnogo soveshchaniya po yadernoy fotografii, Moskva, iyul' 1960g. K. S. Bugomolov and N. A. Persilov, eds. Moscow. Izd-vo AN SSSR, 1962, 66-72.

TEXT: This report on laboratory tests endeavors to reconcile divergences in previous experimental findings on the noninterchangeability (NIC) of time and exposure intensity in achieving a specified degree of photographic blackening with nuclear radiation. Previously I. A. Fomina, née Kovner (ZhETF, v. 20, 1950, 401), had found NIC for medium-energy (30-80 kev) electron beams for times of the order of 1 sec, but none for shorter or longer times, and had also ascertained changes in the NIC effect attributable to changes in development (Zh. nauchn. i prikl. fotogr. i kinematogr., v. 1, 1956, 331) and temperature (ibid., v. 4, 1959, 94). Digby, Firth & Hercock (J. Phot. Sci., v. 1, 1953, 194) and Ray & Stevens (Brit. J. Radiol., v. 26, 1953, 362) had not encountered the effects reported by Fomina (Kovner), but had detected a distinct NIC for much longer exposure times (minutes to days). The present investigation of the NIC for various nuclear radiations was undertaken in connection with several problems of quantitative autoradiography; hence, the

Card 1/4

The phenomenon of the noninterchangeability... S/811/62/000/000/002/003

exposure times run from minutes to weeks and, on exceptional occasions, to months. The tests confirmed the Ray-Stevens conclusions and revealed a profound analogy of the NIC relative to particle action and the NIC for low-intensity light. A flux of β -particles emanating from C^{14} and P^{32} isotopes in activity-graded solutions of Na_2CO_3 and Na_2HPO_4 was used; a decay correction for time was applied to the P^{32} radiation sources. Diapositive, electronographic, and nuclear НИКФИ (NIKFI) P- (R-) type plates (the latter with a 15-20 μ thick emulsion). All development was performed in ID-19, diluted 1:2, at $T=20^{\circ}C$, time - 8 min (mechanical stirring with a soft rubber brush). The relative exposure intensity H was plotted against time, and iso-opaques were drawn. $\log H = 1.0$ was designated to signify the absence of the NIC effect. The regressive nature of the effect is shown by the fact that the degree of the drop in sensitivity with increase in time is greater for lower emulsion sensitivities and ionizing effectiveness of the particles; also, at higher temperatures the drop in sensitivity becomes more pronounced and the time thresholds of the effect are shortened. The effects of other parameters (20-min extended development, soaking in 1% $NaNO_2$ solution prior to exposure, low-pressure exposure at 1 mm Hg) are tabulated. Similar effects were observed under α -particle radiation from a Po^{210} source. Tests were also made with γ -rays emitted by the Co^{60} of a gelatinous wedge, linearly tapered, of $CoCl_2$ (cf. Kuzin, A.M., Mamull', Ya.V., Sbornik "Primeneniye mechenykh atomov v analiticheskoy khimii [The application of tagged atoms in analytical chemistry]," Izd-vo AN SSSR,

Card 2/4

The phenomenon of the noninterchangeability... S/311/62/000/000/002/6/3

1955) to cover an entire linear range of exposure intensity simultaneously. The iso-opaque curves obtained lend themselves to an analytical expression developed by P. V. Meyklar (ZhETF, v. 23, 1952, 217) for low-intensity flare spots. It is concluded that for a given emulsion the minimal number of Ag atoms in the sensitization center, N_0 , is the same for light and for particles of any kind; the activation energy of thermal resorption, U , grows monotonically with the ionizing capacity of the particles, i.e., the thermal destruction of the centers becomes increasingly difficult as the ionizing capacity of the particles generating them increases; lastly, U is always greater for particles than for light. The difference of the U values for various particles is interpreted as a difference in the dispersity of the latent image formed by them, and the magnitude of U itself is regarded as a fully single-valued characteristic of the relative magnitude of the centers in the crystals of a given emulsion. This is the substance of the present study of the NIC with respect to particles. Thanks are expressed to B. P. Sol'titskiy for his assistance with the preparation of the C^{14} and P^{32} sources. There are 5 figures, 2 tables, and 12 references (10 Soviet and the cited 2 English-language papers). Presentation of the paper was followed by a discussion in which L. M. Biberman (senior author associated with I. A. Fomina [Kovner]) took issue with the author's use of Meyklar's low-intensity-light formula as unjustified, asserts that almost any kind of theoretical curve can be fitted to the author's gently sloping experimental data by suitable

Card 3/4

The phenomenon of noninterchangeability...

S/811/62/000/000/002/003

coefficients, and terms the author's conclusions unconvincing and overextended. The author rejects these comments and recommends that the interlocutor defer any criticism pending a perusal of the full paper.

TITLE: Effect of polyethylene glycol on nuclear photographic emulsions 15	
SOURCE: Zhurnal nauchnoy i prikladnoy fotografii i kinematografii, v. 9, no. 4, 1964, 300-302	
TOPIC TAGS: photographic chemistry, photographic chemical, nuclear emulsion, photosensitivity, glycol	
ABSTRACT: Adding polyethylene glycol (PEG) to various photographic emulsions can substantially increase their light-sensitivity. The effect of PEG on various nuclear emulsions differing in characteristics, was tested both for exposure to light and to particles. It was added to emulsion in amounts from 0.8 to 3.2 grams per liter of emulsion. The experiments were performed on two relativistic emulsion's - the R-NIKFI type and the extra fine grain PR-2, and two less sensitive emulsions, -- the Ya-2 and A-2 type. After glazing, the emulsion layers were exposed to low intensity light (exposure time = 45 seconds) through a graduated wedge, and also irradiated with Po^{210} alpha-particles, C^{14} beta-radiation in a special sensitometer, and by a beam of relativistic electrons. The results showed that the sensitivity to Card 1/2	

L 63819-65

ACCESSION NR: AP5011723

particles was not appreciably increased in any case. In contrast, the increase in light sensitivity in all cases was quite distinct. Another feature of the light-sensitivity results was that the increment in sensitivity bore no relationship to the original sensitivity and the extent of chemical sensitization of emulsions, but dropped off clearly with decreasing size of microcrystals. Therefore, the effect of MEG is related not to the reactions in which sensitivity centers participate, but with reactions in which the entire bulk or surface of the AgHal crystal participates.

TITLE: 16th all-union conference on scientific photography devoted to nuclear photography

SOURCE: Zhurnal nauchnoy i prikladnoy Fotografii i kinematografii.
v. 10, no. 1, 1965, 76-79

TOPIC TAGS: scientific photography, photographic emulsion, nuclear photography

ABSTRACT: The conference was the first to be specially devoted to nuclear photography, and was held from 30 September through 3 October 1964 in Leningrad. Approximately 150 persons participated, representing 19 institutions and organizations from Moscow, Leningrad, Dubna, Yerevan, Kazan", and other cities. Twenty-five papers were read and discussed at six sessions held in five sections. The first

section "Photographic action of charged particles" included three papers: "Dependence of ionizing ability on the momentum for ultra-relativistic electrons and positrons" by G. B. Zhdanov, M. I. Tret'yakova, and M. N. Shcherbakova; "Investigation of the influence of intensity of an electron beam and the temperature on the sensitivity of photographic emulsions" by K. S. Bogomolov, I. A. Fomina, and V. S. Markova and "Direct method of determining the microsensitivity of AgBr microcrystals to charged particles" by I. M. Kuks. The second section was devoted to "Preparation of photographic materials for nuclear research" and included four papers: "Properties of type PR-2 fine-grain emulsion" by N. A. Perfilov, N. R. Novikova, V. I. Zakharov, and Ye. V. Fadina, "Use of synthetic polymers in the preparation of fine-grain nuclear emulsions" by N. R. Novikova, V. I. Zakharov and Ye. V. Fadina, "On sensitivity centers and development centers of unsensitized nuclear emulsions" by D. M. Samoylovich, and "Theoretical justification of the choice of developing substance for inclusion in the nuclear emulsion" by Ya. M. Veprik, A. P. Zhdanov,

G. G. Martysh, and L. I. Shur.⁹ The third section "Investigation of the properties of nuclear emulsions and their preliminary processing" included seven papers: "Kinetics of reduction of silver ions on gold-silver centers" by Ya. M. Veprik, "Sensitivity centers of emulsions successively sensitized with gold and triethylene amine" and "comparative hypersensitization of nuclear emulsions by triethylene amine and other alkali sensitizers," by D. M. Samoylovich, I. V. Ardashev and Ye. S. Barinova, "Regression of sensitivity and of the latent image in photographic emulsions for nuclear and light radiations" by A. L. Kartuzhanskiy, A. F. Yurchenko, I. I. Shur, and G. G. Martysh, "Mechanism for the influence of moisture on the stability of sensitivity centers and of the latent image",¹⁰ by K. M. Romanovskaya and K. S. Bogomolov, "Registration of alpha stars from radioactive nuclei and time discrimination of alpha-particle tracks in nuclear emulsions" by I. B. Berkovich, A. P. Zhdanov, and L. I. Shur, and "Enrichment of nuclear emulsions by hydrogen nuclei" by L. N. Bokova and L. G. Kriventsova. The fourth section dealt with "Photographic processing of nuclear emulsions" and included six papers: "Penetration of compo-

TITLE: Possibility of discriminating between types of radiation recorded in the form of photographic density

SOURCE: AN SSSR. Komissiya po khimii fotograficheskikh protsessov. Uspekhi nauchnoy fotografii, v. 12, 1966. Yadernaya fotografiya (Nuclear photography), 91-95

TOPIC TAGS: nuclear emulsion, particle track, track analysis, radiation detecting device

ABSTRACT: The author analyzes various methods of identifying a detected particle by ascertaining the nature of the track it leaves in the emulsion. These are aimed at separating the useful density from that of the background, determining means of intensifying the useful density without similar intensification of the background, weakening the background density without a similar weakening of the useful density, or a combination of these procedures. Differences between this type of discrimination and other known methods used in nuclear photography, of modifying the widths and optical densities or the number of grains per unit length in the tracks of different particles are described. The methods discussed are discrimination prior to exposure, during the

Card 1/2

ACC NR: AT7000924

time of the exposure, between exposure and development, during the development, and after development. The only possibility of creating conditions favoring discrimination prior to exposure is to make use of the unequal role of deep and shallow traps for electrons under the influence of different radiation. Discrimination during the time of exposure would possibly consist of varying the temperature conditions in the emulsion. There are more opportunities for discrimination in the interval between exposure and development, such as the Herschel effect, thermal or chemical (accelerated) regression, oxidation of the latent image, and others. There is little that can be done during development, although some variant of physical development may contribute to discrimination during development. Discrimination after the completion of the chemical-photographic processing is possible only if some electron-microscopic differences can be revealed between the tracks produced by different types of radiation. It is pointed out in conclusion that each of the methods has strong limitations.

AUTHOR: Manuilov, V., Kozyrev, A., and Kartuzov, I.

TITLE: The "Melodiya" Tape Recorder (Magnitofon "Melodiya")

PERIODICAL: Radio, 1957, Nr 3, pp 42-45 (USSR)

ABSTRACT: Soviet industry has built and is releasing for sale a new portable tape recorder, "Melodiya." Its performance meets the requirements of the fourth group of GOST 8088-56. Type 2 or SN tape should be used with the new double-track tape recorder. At 9.53 cm/sec tape speed, the apparatus can record and reproduce a frequency band of 100 to 6,000 cps with 3 db irregularity at 400 cps. The overall recording-and-reproduction distortion factor is 2.8% at an output of 1.5 w. The signal-noise ratio is 38 db. Sensitivity of the recorder at 1,000 cps: at microphone terminals, 0.5 mv; at "phono" terminals, 100 mv; at "radio" terminals, 3 volts; and at wire-broadcast-line terminals, 10 volts. Outputs for an external amplifier and an external speaker are provided. Output voltage for an external amplifier is 775 mv on 30 kohms, and output voltage for the external speaker is 2.15 volts on 3 ohms. Tone control has a range of 20 db at 6,000 cps. The erasing and magnetizing HF oscillator functions at 50 kc. A visual recording-level indicator has a time constant of 250 m/sec. Up

Card 1/3

107-57-3-46/64

The "Melodiya" Tape Recorder

to 250 m of tape can be accommodated on a reel, which amounts to ninety minutes of recording time on both tracks. The time of fast forward or fast rewind motion is under 100 seconds. A pointer-type selection locator is provided for rough determination of tape length. Three knobs and a keyboard switch serve to control the recorder. Cabinet dimensions are 200 x 300 x 370 mm. The recorder consumption is 65 w for recording or reproducing, and 100 w for fast rewinding, AC, 110, 127, 200, or 220 volts. The performance remains good within line-voltage fluctuations of +5% -- 10%. A continuous operation for three hours is permissible. A dynamic MD-55 microphone, two connecting cables, three reels, and spare erasing and universal heads are supplied with the recorder. A pictorial diagram given in the article shows the mechanical construction of the recorder. A simplified circuit diagram of the amplifier and of the recorder proper is also presented. Recording and reproduction frequency response curves are shown in the band of 60 cps to 10,000 cps. The following tubes are used: two 6N2P, two 6P1P, and one 3-3-488. A selenium type ABC-80-260 rectifier feeds the anodes. Magnetic head, coil, and transformer

TITLE: Low-frequency logical elements based on ferrite-diode transformer circuits

SOURCE: AN SSSR. Institut avtomatiki i telemekhaniki. Teoriya i primeneniye avtomaticheskikh sistem (Theory and application of automatic systems). Moscow, Izd-vo Nauka, 1964, 243-253

TOPIC TAGS: logical element, ferrite diode element, low frequency logical element

ABSTRACT: A multifunctional multi-input logical element is described which is intended for realizing a sum of products or a product of sums with a partial or total inversion (or some other complicated function). The new multifunctional element includes a unit generator, a repeater, and several control elements.

Card 1/2

L 22416-65

according to the number of inputs; methods of voltage compensation and shunting a winding in recording I are used. Various logical operations including "AND-negation," "OR-negation," "negative OR," implication, modulus-2 addition, etc., are possible. These logical devices based on the new multifunctional element are considered: a dynamic trigger (as a storage unit), a counter-input dynamic trigger, a delay unit, a single-digit code converter, and a binary counter. The multifunctional element "was developed jointly with R. V. Bilik and V. A. Zhozhikashvili." Orig. art. has: 15 figures and 15 formulas.

TITLE: Reliability of ferrite-diode logical elements 16c

SOURCE: Vsesoyuznoye soveshchaniye po magnitnym elementam avtomatiki i vychislitel'noy tekhniki. 9th, Yerevan, 1963. Magnitnyye tsifrovyye elementy (Magnetic digital elements); doklady soveshchaniya. Moscow, Izd-vo Nauka, 1965, 165-173

TOPIC TAGS: logical element, ferrite diode element

ABSTRACT: A mathematical model of reliability of logical elements that have more than 2 inputs is offered. The model permits evaluating the consequences of failures of individual elements due to short-circuits or breaks with an allowance for the role of the element in the equipment. Also, the reasonable minimum number of inputs of the logical element which still guarantees its specified reliability can be determined. The above approach to reliability evaluation is demonstrated by an example of an

Card 1/2

L 28057-66

ACC NR: AT6002985

AND-element with k inputs. Differential equations for the probability of various states of the logical element are set up on the basis of a "diagram of states" which shows the consequences of failures of individual components. Solved by a conventional method (e.g., Laplace's transforms), the differential equations yield a formula for the probability that the element in question would be able to operate with a known reduced number of inputs (less than k). A numerical example with a 3-input AND-element illustrates the method. Procedural steps in the reliability calculations are outlined. Orig. art. has: 4 figures, 19 formulas, and 3 tables.

TITLE: Ferrite-diode logical elements for remote control and telemetry

SOURCE: Vsesoyuznoye soveshchaniye po magnitnym elementam avtomatiki i vychislitel'noy tekhniki, 9th, Yerevan, 1963. Magnitnyye tsifrovyye elementy (Magnetic digital elements); doklady soveshchaniya. Moscow, Izd-vo Nauka, 1965, 156-164

TOPIC TAGS: logical element, remote control, telemetry

ABSTRACT: Several ferrite-core-plus-diode logical elements and switching circuits are described; the experimental elements used VT-2 and K-65, 10 x 6 x 2.5-mm ferrite cores. A 4-core AND-gate is briefly described, and the plots of power, current, and current ratio vs. supply voltage for 2-10 inputs are presented. A 3-core NOT gate (inverter) is briefly described. A circuit diagram is shown that carries out the Scheffer operation: $f = x \wedge y = x \vee y$. Also, a circuit diagram for a

TITLE: Measurement of the diffusion length of minority carriers in InSb

PERIODICAL: Fizika tverdogo tela, v. 3, no. 10, 1961, 2973 - 2980

TEXT: Since the characteristics of InSb infrared receivers depend considerably on the minority-carrier lifetime τ (or their diffusion length L), measurement of these quantities is of great interest. The authors used the Waldes method to determine L and τ in n- and p-type InSb single crystals having impurity concentrations between 10^{12} and 10^{16} cm^{-3} . L was determined by the Waldes light-probe method. For weak illumination intensities, when the collector photo-emf $V \ll kT/5e$ (e - electron charge), V is proportional to the light-induced minority carrier concentration. When the surface recombination rate is small, $V = V_0 \exp(-x/L)$ in the dark (x - distance from the illuminated region). This relation holds for one-dimensional geometry. In axisymmetric geometry $V = V_0 \exp(-x/L)/\sqrt{x}$. It was to be found experimentally which of these formulas has to be applied.

Card 1/34

Measurement of the diffusion...

29688 S/181/61/003/010/010/036
B102/B108

The 0.2 - 2 mm thick test pieces were polished and then etched with CP-4A (SR-4A). They were placed in a vacuum cryostat with an NaCl window. The light incident on the specimen was interrupted by an 800-cps chopper. A tungsten or phosphor-bronze point served as a collector contact; a 28-M Ω (28-IM) amplifier was used to measure the variable photo-emf on it. The measurements were made between 100 and 200°K. The carrier concentration in the specimens at 77°K was determined from the Hall effect, L was determined from the inclination of the straight line $\log V = f(x)$. τ was determined from $\tau = L^2/D$ where

$$D = D_p \frac{b(1 + \frac{p_0}{n_0})}{b + \frac{p_0}{n_0}}, \quad (4)$$

$D_p = u_p kT/e$ being the hole diffusion coefficient, $b = u_n/u_p$, the mobility ratio, p_0 and n_0 the equilibrium concentrations. For intrinsic conductivity $D = 2bD_p/(b+1)$. In the case of impurity conductivity, $D = D_p$ for n-type, and $D = D_n = u_n kT/e$ for p-type specimens. The carrier concentration in the intrinsic-conductivity region of InSb is given by

Card 2/5L

Measurement of the diffusion...

29688 S/181/61/003/010/010/036
B102/B108

$n_i \approx 6 \cdot 10^{14} T^{3/2} \exp(-1510/T)$. The temperature dependence of τ can be seen in Fig. 4. When temperature drops from 170 to 120°K, τ decreases to less than one hundredth its value. In this range the temperature dependence of τ obeys the Shockley-Reed law. It is shown that the experimental curves $\tau = f(1/T)$ agree with the formula

$$\tau = \frac{2\tau_i n_i}{n_0 + p_0} = \frac{2\tau_i n_i}{\sqrt{4n_i^2 + N_{n,p}'^2}}, \quad (12)$$

which holds for a neutral crystal and radiative recombination. $N_{n,p}$ are the majority-carrier concentrations in an n- or p-type crystal in the region of impurity conductivity. $\tau = 2\tau_i n_i / N_{n,p}$ holds for the impurity-conductivity region ($n_i \ll N_{n,p}$). The straight line corresponding to Auger recombination is too steep. Results: (1) No correlation was found between L and the impurity concentration. (2) The data agree with the radiative-recombination theory for $b \approx 600 - 700$. (3) The difficulties arising in the interpretation of the results may be due to an inaccurate measurement of L and an inaccurate calculation of τ_i . There are 5 figures, 1 table, and 24 references: 9 Soviet and 15 non-Soviet. The three most recent refer-

TITLE: Observations on tidal variations of the force of gravity in Tbilisi ✓

SOURCE: AN GruzSSR. Soobshcheniya, v. 36, no. 3, 1964, 561-564

TOPIC TAGS: geophysics, geophysical research, tide, gravitational force/ Askaniya
Gs-11 No. 144 gravimeter

ABSTRACT: A gravimetric station was established in Tbilisi in 1960 for the purpose of observing land tide variations of the force of gravity. Three series of observations were organized: the first from February 8, 1960, to March 10, 1960; the second from May 23, 1960, to August 17, 1960; and the third from January 31, 1961, to April 1, 1961. The test measurements were conducted in an underground chamber in carefully controlled temperatures and humidity; an Askaniya gravimeter, Gs-11 No. 144, was used in the measurements. A cautious procedure of instrument control and calibration was observed for each test series. The observations were carried out by both the first and second methods of V. P. Fertser (Garmnicheskij analiz prilivov. Izv. AN SSSR, ser. geofiz., No. 8, 1958, and Garmnicheskij analiz 50-dnevnykh ryadov nablyudenij prilivnykh izmenenij sily tyazhesti. "Izuchenije zemnykh

TITLE: Observations on tidal deformations of the earth by means of a horizontal extensometer in Tbilisi

SOURCE: AN SSSR. Izvestiya. Fizika zemli, no. 2, 1965, 75-79

TOPIC TAGS: tide, [✓]earth figure, deformation meter, quartz

ABSTRACT: Two large quartz extensometers were set up in the underground observatory of the Institut geofiziki Gruzinskoy AN (Geophysical Institute of the Georgian Academy of Sciences) in Tbilisi in 1962. The tunnel (100 m long) in which the instruments were placed is in tuffaceous sandstones and mudstone, and is lined with a layer of concrete 30-40 cm thick. One extensometer, with a 41-m base, is set up 40 m from the tunnel entrance. Its sensitivity is $0.22 \cdot 10^{-8}$ mm, and it is oriented N 60° E. The other instrument, with a 14.5-m base, is set up 70 m from the entrance. Its sensitivity is $0.7 \cdot 10^{-8}$ mm, and it is oriented N 30° W. The instruments record the displacement of two fixed points on the earth's surface, the distance between

Card 1/2

L 62220-65
ACCESSION NR: AF5017165

the points being the instrumental base. Connection with the ground is made through rigid rods (tubes of transparent quartz glass, 3 m. long, 40 mm in diameter, and with walls 2-3 mm thick). A continuous record was obtained from only the N 30° W instrument because of moisture damage to the other. For June-September 1963 this instrument showed a tidal displacement amounting to $3.5 \cdot 10^{-8}$ mm. The durations of the fluctuations were subjected to harmonic analysis to isolate the tidal component. The ratio of elastic constants (Love number to Shida number) was found to be 6.6. Assuming the first to be 0.5-0.6, the second would then be 0.08-0.09, a value that is in good agreement with other authors. The value of the Love number, computed separately, is found to be lower than that given by gravimetric data and inclinometer measurements. It is possible that the variation may be due to local peculiarities in deformation. Orig. art. has: 2 figures, 2 tables, and 8 formulas.

AUTHOR: Aronovich, G. V. (Gor'kiy, Moscow); Kartvelishvili, N. A. (Gor'kiy, Moscow)

TITLE: Application of the theory of stability to problems in static and dynamic stability of power systems

SOURCE: AN SSSR. Inzhetiya. Mekhanika i mashinostroyeniye, no. 5, 1964, 131-136

TOPIC TAGS: electric power production, solid mechanics

Abstract: The problem of reliability of a power system is presently considered on the one hand as a problem in determining necessary power and energy reserves and on the other -- as a problem in stability of the stationary conditions of the system, the results of solutions of these two problems being used almost independently of each other. Stability problems are formulated as determination of the stability or instability of the system with given parameters in relation to a given disturbance, without determining the probability characteristics of the loss of stability. For electric power consumers, there is no fundamental difference between loss of stability and other emergencies, and these disruptions in stability should be taken into account in estimating the total probability of continuity in electric supply in the same way as breakdowns in station

Card 1/2

L 58475-65

ACCESSION NR: AP5017197

equipment, breaks in transmission lines and other accidents. The problem of reliability is, in the final analysis, a problem of the economy of a power system since a disruption in the electric power supply to the consumer leads to economic losses or inconveniences to the population but, with rare exceptions, does not bring catastrophe or other completely inadmissible results. The authors show how the concepts in the general theory of stability may be applied to problems in reliability of power systems. Orig. art. has 13 formulas.

"Specifications of the Quality of Automatic Regulation," N. A. Kartvelishvili, 3 pp

"Dok Ak Nauk SSSR" Vol LXI, No 1

The transitional process in a regulating system is described by the equation of the object regulated

$$M(p)S + N(p)\bar{\Phi} = Q(p)\bar{I}$$

and the equation of the regulator

$$A(p)\bar{\Phi} = B(p)S,$$

8/49RT3

USSR/Electronics (Contd)

Jul 48

in which p is Heaviside's operator. $S, \bar{I}, \bar{\Phi}$ are operator representations and the regulating reaction, excitation reaction and deviations of the regulated quantity from the normal value. M, N, Q are functions of p , the parameters of which depend only on the object regulated. A, B are functions of p , the parameters of which depend only on the regulator. Author deduces criterion for quality of regulation and constructs a vector diagram showing his results. Submitted 15 Mar 1948.
